

Abstract of the Invention

A bucket has an upper opening and an interior cavity, a floor having a rear portion and a front portion within the body, and a handle extending upwardly from a first side the body. The handle has a gripping member and a pair of side portions that define a receiver opening, and the handle does not materially extend over the receiver opening. The body is eccentrically weighted by a weight member attached to the first side of the body so that the bucket is balanced when suspended by the handle.
